

Abstract

Pythia is a speech interface for UNR's selfdriving car that allows intuitive two-way communication between driver and vehicle. Users can obtain real-time information about obstacle detection and vehicle status simply by asking - at no point needing to take their eyes off the road. The speech interface allows the car to make announcements when critical events occur, such as pedestrians entering the vehicle's path. By providing a simple and easily extensible interface to the vehicle, Pythia allows drivers to safely and quickly check that the vehicle is operating correctly.

Hardware

The speech interface has been developed specifically for UNR's self-driving car, a Lincoln MKZ shown in Figure 1. It is equipped with an on-board computer running Ubuntu that can access the vehicle CANBUS (controller area network).

The microphone chosen to capture voice for the interface is ReSpeaker Mic Array v2.0, shown in Figure 2. It is small enough to fit easily on the car dashboard and is able to detect the direction of the loudest audio input, helping reduce noise interference.

Interface Functionality

The primary functionality of the interface is responding to questions regarding the status of the car and its neighboring environment. Users can ask questions on obstacle detection, vehicle status, and odometry data. The GUI, shown in Figure 3, displays what the car most recently heard and said.

interface is designed with The flexibility in mind. The text size of the interface can be changed using a slider. The voice of the interface can be changed using a drop down menu. The wake word (used to activate the interface) can be set to Figure 3. Interface main menu any valid text. (top) and settings (bottom)

Event Driven Alerts

The interface provides announcements for situations where the driver should be immediately notified, such as a pedestrian entering the vehicle's path. Figure 4 shows an example where a pedestrian enters a crosswalk in front of the vehicle, triggering an announcement from the interface.

Open Source

As part of the Pythia project, an open source speech recognition package for ROS, the Robot Operating System, was developed and made publicly available. The package, shown in Figure 5, is now being used by several roboticists outside of UNR.

README.md

unr_deepspeech - Speech Recognition for Robots

The unr_deepspeech package is a ROS node providing speech-to-text for robots. It does this by wrapping Mozilla's TensorFlow implementation of Baidu's DeepSpeech network for speech recognition. The system works entirely offline, and rovides high-quality transcriptions using pretrained neural networks available from Mozilla. It also aims to be easy to install, with minimal configuration required to produce acceptable transcriptions The package has been tested in ROS Kinetic and ROS Melodic

Future Development

Currently, Pythia receives status information from the vehicle and camera, and communicates it to the user. This provides an accurate representation of what the car knows, but it does not explain how the car is making decisions based on the data. To fulfill the project goal of allowing the driver to understand the car's intentions, the interface will need to be integrated with the car's planner.

Additionally, the interface needs to be optimized for a faster response time. Delays between questions and answers can reach a maximum of 8 seconds, which is too large for time-sensitive information.
